CESC16 Detailed Instructions

This document contains an in-depth description of all the machine instructions supported by the CESC16 computer, as well as the macros provided by the assembler.

ASSEMBLER MNEMONIC	Machine code (binary)	Pseudocode (C-style)
--------------------	--------------------------	-------------------------

C-style Pseudocode notation:

- ALU(A, B) ALU operation between A (first operand) and B (second operand)
- P Flags get updated
- RAM[Addr] Access RAM at a given address (Addr)
- ROM[Addr][W] Access a word W (1=Upper, 0=Lower) of ROM at a given address (Addr)
 push(A) Push a given register A to the stack. It's the same as RAM[--sp]=A
 A=pop() Pop a given register A from the stack. It's the same as A=RAM[sp++]

Macros notation:

- [Operand] Either a register rB, immediate Imm, or memory address: (Addr) or (rB)
- The mnemonic on the left side of the arrow gets replaced by the instruction(s) on the right side of the arrow: MACRO → Translated Instructions

DETAILED INSTRUCTIONS:

ALU Operations:

Register operand:

[ALU] rD, rA, rB	X0000FFFDDDDAAAA XXXXXXXXXXXBBBB	rD = ALU(rA, rB) □
------------------	-------------------------------------	-----------------------

Immediate operand:

[ALU] rD, rA, Imm16	X0001FFFDDDDAAAA	rD = ALU(rA, Imm16) □
---------------------	------------------	--------------------------

Direct addressing:

[ALU] rD, rA, (Addr16)	X0010FFFDDDDAAAA @@@@@@@@@@@@@@@@@	rD = ALU(rA, RAM[Addr16])
------------------------	---------------------------------------	---------------------------

Indirect addressing:

[ALU] rD, rA, (rB)	X0011FFFDDDDAAAA XXXXXXXXXXXXBBBB	rD = ALU(rA, RAM[rB])
--------------------	--------------------------------------	-----------------------

Operations on each clock cycle (Register and Immediate):

Fetch instruction + 1st operand Fetch argument (2nd operand)	ALU operation and store sult in register file
--	---

Operations on each clock cycle (Direct and Indirect):

Fetch instruction +	Fetch argument and	Fetch 2nd operand from	Perform ALU op. and
1st operand	compute address	memory	store result in reg. file

Description:

Performs an ALU operation as indicated by the 3 Funct bits, using the <u>contents of rA</u> as first operand and either the <u>contents of rB</u>, a <u>16 bit immediate</u> or the contents of a <u>memory address</u> as second operand. The result of the operation is stored in rD and the flags are updated accordingly. See table in main documentation for ALU operations, mnemonics and descriptions.

Remarks about ALU operations:

- Carry and oVerflow flags are undefined after all operations except add, sub, addc and subb.
- The mov instruction doesn't require the first operand (rA), doesn't update the flags (see movf macro for this purpose) and takes only 2 clock cycles (Register and Immediate) or 3 clock cycles (Direct and Indirect).
- The mov instruction with Direct and Indirect addessing can be used as a substitute for the 1w instruction. Using the dedicated 1w/1b instructions is recommended, since they use the superior indexed addressing and 1b allows loading single bytes. However, if indexed addressing and byte addressing aren't needed, using mov may improve code readability.

Examples:

mov t0, t1	The value stored in t1 gets copied into t0. The value at t1 and the flags are unchanged.
mov t0, 0x1234	The value stored in t0 becomes 0x1234. Flags are preserved.
and t0, t1, t2	Perform a logic AND between the contents of t1 and t2. Store result into t0. The values at t1 and t2 remain unchanged.
sub t0, t1, (123)	Fetch the contents stored at address 123 (0x7B) and subtract them from the contents stored at t1. Store the result in t0 (operands remain unchanged).
addc t0, t1, (t2)	Fetch the contents pointed by register t2 and add them to the contents of t1. Add 1 to result if Carry bit is set. Store result in t0 (operands are unchanged).

Macros: Move and update Flags:	movf rD, [Operand]	\rightarrow	add rD, zero, [Operand]
Negate register (bitwise NOT):	not rD, rA	\rightarrow	xor rD, rA, 0xFFFF
Bitwise NAND, NOR and XNOR: nand/nor/xnor		\rightarrow	and/or/xor rD, rA, [Operand] not rD, rD
Shift Left with Carry (1 bit):	sllc rD, rA	\rightarrow	addc rD, rA, rA
Compare register to operand:	cmp rA, [Operand]	\rightarrow	sub zero, rA, [Operand]
Test masked register:	mask rA, [Operand]	\rightarrow	and zero, rA, [Operand]
Test register (or memory):	test [Operand]	\rightarrow	movf zero, [Operand]
Clear flags:	clf	\rightarrow	movf zero, 0x0001
No operation*:	nop	\rightarrow	mov zero, zero

^{*} There are many alternative expansions for nop. This one is encoded as all zeros (0x0000).

ALU Operations (destination in memory):

Direct addressing

[ALU] (Addr16), rA	X0100FFFXXXXAAAA @@@@@@@@@@@@@@@@@	RAM[Addr16] = ALU(RAM[Addr16], rA) 戸
--------------------	---------------------------------------	---

Indirect addressing:

[ALU] (rA), rB	X0101FFFXXXXAAAA XXXXXXXXXXXBBBB	RAM[rA] = ALU(RAM[rA], rB) □
----------------	-------------------------------------	---------------------------------

Operations on each clock cycle:

Fetch instruction Fetch argument and compute address	Fetch 1st operand from memory	Perform ALU op. and store result in memory
--	-------------------------------	--

Description:

Performs an ALU operation as indicated by the 3 Funct bits, using the contents of a memory address (direct or indirect addressing) as first operand and a register as second operand.

The result of the operation is stored in the <u>same address as the first operand</u> and the flags are updated accordingly. See table in main documentation for ALU operations, mnemonics and descriptions.

Remarks about memory ALU operations:

- Carry and oVerflow flags are undefined after all operations except add, sub, addc and subb.
- The decoded memory address is used for both <u>first operand</u> and <u>destination</u>. The second operand must be a register (no Memory-Memory or Memory-Immediate operations). If those restrictions can't be met, considering loading the needed value to a temporary register first.
- The mov instruction doesn't update the flags (see movf macro for this purpose) and takes only 3 clock cycles.
- The mov instruction can be used as a substitute for the sw instruction. Using the dedicated sw instruction is recommended, since it uses the superior indexed addressing. However, if indexed addressing isn't needed, using mov is 1 cycle faster and may improve code readability.

Examples:

mov (123), a1	Store the contents of a1 into memory location 123 (0x7B). The value at a1 is unchanged. Flags are preserved.
mov (t0), zero	The memory contents that are being pointed by t0 become 0x0000 (the contents of zero get copied). Flags are preserved.
xor (6), s1	Perform a logic XOR between the contents at memory address 6 and the contents stored in s1. Store result into address 6 (s1 remains unchanged).
add (sp), a1	Increment the top of the stack by the amount stored in a1. The contents of a1 and sp remain unchanged.
subb (t2), t1	Fetch the contents pointed by register t2 and add them to the contents of t1. Add 1 to result if Carry bit is set. Store result in t0 (operands are unchanged).

Shifts:

Shift Left Logical:

	sll rD, rA, Imm4	X011 <mark>IIIIDDDD</mark> AAAA XXXXXXXXXXXXXXXX	rD = rA< <imm4 th="" □<=""></imm4>
--	------------------	---	------------------------------------

Shift Right Logical:

srl rD, rA, Imm4	X100IIIIDDDDAAAA XXXXXXXXXXXXXXXXX	rD = rA>>Imm4 戸 (unsigned)
------------------	---------------------------------------	-------------------------------

Shift Right Arithmetic:

sra rD, rA, Imm4	X101IIIIDDDDAAAA XXXXXXXXXXXXXXXXX	$rD = rA >> Imm4 \bigcap$ (signed)
------------------	---------------------------------------	------------------------------------

Operations on each clock cycle:

Fetch instruction + operand (rA)	Shift 1 position	Shift 1 position		Shift 1 position and store result
----------------------------------	------------------	------------------	--	-----------------------------------

Description:

The contents of rA get shifted (left or right) as many bits as indicated by Imm4.

- s11: bits get shifted to the left and filled with zeros.
- srl: bits get shifted to the right and filled with zeros.
- sra: bits get shifted to the right and the sign is extended.

Flags are updated (Carry and oVerflow flags are undefined) and the result is stored in rD.

Remarks about shifts:

- Memory contents can't be shifted directly and must be copied to/from a temporary register.
- Bit shifts are the only instructions with variable clock durations. Each shifted bit takes 1 clock cycle, plus 1 extra clock for fetching.
- The ISA allows shifting 0 bits but, since it has no practical use, it can be considered an illegal instruction. The computer will interpret a shift of 0 bits as a NOP.

Load/Store data from/to memory:

Load Word:

lw rD, Imm16(rA)	X1100000DDDAAAA IIIIIIIIIIIIII	rD = RAM[rA+Imm16]
Load Byte:		
lb rD, Imm16(rA)	X1100001DDDDAAAA IIIIIIIIIIIIII	rD = byte(RAM[rA+Imm16])
Store Word:		
sw rB, Imm16(rA)	X1100010BBBBAAAA	RAM[rA+Imm16] = rB

Operations on each clock cycle:

Fetch instruction	Fetch offset and compute address	Only in sw: Fetch rB	Read or Write data memory
-------------------	----------------------------------	----------------------	------------------------------

Description:

The contents of rA are <u>added</u> to an immediate offset to get a memory address. Then, the contents of 1 register is transfered to or from <u>data memory (RAM)</u>:

- lw: the 16-bit word stored in memory at the given address gets copied into rD (memory contents are unchanged).
- 1b: the same as a 1w, but only the <u>lower 8 bits</u> are fetched and the <u>sign is extended</u>.
- sw: the 16-bit word stored in rB gets copied into memory at the given address (rB is unchanged).

Remarks about load/store:

- The constant zero register can be used as rA in order to access an absolute address.
- A 1bu (Load Byte Unsigned) macro can be implemented with a mask (set upper 8 bits to 0).
- Memory access is <u>not</u> Byte-Oriented and Data Memory is 16 bit wide:
 - There is no way to access only the upper 8 bits of the word at a memory address (other than using 1w and shifting 8 positions with sr1).
 - It doesn't matter if we want to store a byte or a 16 bit word, both take the same amount of space in memory (1 word).
 - A sb (Store Byte) instruction isn't needed, the only thing that matters is how the data is interpreted when the Load is performed (choosing between 1w, 1b and 1bu). However, sb can be used as an alias to sw to improve code clarity.

Macros:

Load Byte Unsigned: movf rD, [Operand] \rightarrow lb rD, Imm16(rA) and rD, rD, 0x00FF Store Byte: sb rB, Imm16(rA) \rightarrow sw rB, Imm16(rA)

Swap register with memory:

swap rD, Imm16(rA)	X1100011DDDDAAAA	<pre>temp = rD; rD = RAM[rA+Imm16]; RAM[rA+Imm16] = temp</pre>
--------------------	------------------	--

Operations on each clock cycle:

Fetch instruction	Fetch offset and	Fetch rB	Read data	Write data	
1 etch instruction	compute address	(same as rD)	memory	memory	

Description:

Swaps the contents of rD and the contents stored at an address (with offset) of <u>data memory (RAM)</u>. A lw and a sw are performed simultaneously to and from rD.

Peek program memory:

peek rD, $Imm16(rA)$, W $X110010WDDDDAAAA$ $IIIIIIIIIIIIIIIIIIIIIIIIIIIIIIIII$	peek rD, Imm16(rA),
---	---------------------

Operations on each clock cycle:

Fetch instruction	Fetch offset and compute address	Read program memory
-------------------	----------------------------------	---------------------

Description:

Loads into rD the contents <u>from program memory (ROM)</u> at the address contained by rA. Since the program memory is 32 bits wide, Imm1 indicates which 16-bit word will be fetched:

- W=1: Most significant bits get fetched (instruction opcode).
- W=0: Least significant bits get fetched (instruction argument).

The assembler uses big endian encoding. Therefore, when peek is used to load 16-bit constants, the most significant bits (W=1) correspond to the <u>first word (lower address)</u> and the least significant bits (W=0) correspond to the <u>second word (higher address)</u>.

Stack Push and Pop:

Push register to Stack:

X1100110XXXX0001 XXXXXXXXXXXBBBB	<pre>RAM[sp] = rB (push(rB))</pre>
X1100111DDDD00001 XXXXXXXXXXXXXXXXX	rD = RAM[sp++] (rD = pop())
X1111010XXXX0001 XXXXXXXXXXXXXXX	<pre>push(readFlags())</pre>
X1111011XXXX0001 XXXXXXXXXXXXXXXX	<pre>writeFlags(pop())</pre>
	XXXXXXXXXXXXBBBB X1100111DDDD0001

Operations on each clock cycle:

Fetch instruction	Fetch and update Stack Pointer Only in push: Fetch rB	Read/Write data memory
-------------------	---	------------------------

Description:

- push pushes the contents of rA into the stack: sp is decremented by 1 and rA is stored at the new address pointed by sp.
- pop pops the top of the stack into rD: loads the contents pointed by sp into rD and then sp is incremented by 1.
- pushf and popf work the same way, but they store and load the flags (status register). This isn't usually needed for regular subroutines, but it's indispensable to use this instructions in an interrupt handler.

<u>Warning</u>: 1w/sw instructions can also be used to access the stack without the limitations of push/pop (by using sp as address), but you shouldn't use both methods at once: since push/pop affect sp, the offset you have to use in 1w/sw to access each variable will change. Unless you know what you are doing, that will most likely lead to bugs.

Remarks about interrupt handlers: An interrupt handler *must* push the flags and <u>all</u> registers it's going to use (not just the safe registers). However, all of this is <u>already done by the OS</u> before handing over control to the user's interrupt handler, which <u>can treat the registers and flags as if it was a regular subroutine</u> (that is, it only needs to push and pop *safe* registers).

Conditional Jumps:

Jump to immediate address:

[JMP] Addr16	X1101FFFXXXXXXXX @@@@@@@@@@@@@@@@@	if(condition) PC = Addr16
--------------	---------------------------------------	---------------------------

Jump to register:

Operations on each clock cycle:

Fetch instruction	Check flags. Only if condition is true: Load new address into PC
-------------------	---

Description:

Checks the condition indicated by the 3 Funct bits, then jumps to an immediate address (or the addres stored in rA) only if the condition is true.

Therefore, the next executed instruction is pointed by:

- Addr16 or rA, if the jump condition is met. The j instruction is always performed.
- PC+1, if the jump condition is not met.

The jump condition is checked using the flags, which depend on the <u>last ALU operation</u>.

Conditional jumps (and macros) can be separated in 2 groups:

- Check result of last operation: jz, jnz, jc, jnc, jb, jnb
- Compare 2 integers (<u>must</u> be executed right after a CMP instruction): jeq, jne, jlt, jle, jltu, jleu

Macros:

Jump if Borrow: jb addr \rightarrow jnc addr Jump if Not Borrow: jnb addr \rightarrow jc addr

Jump if Equal: jeq $addr \rightarrow jz \ addr$

Jump if Not Equal: jne $addr \rightarrow jnz \ addr$

Jump if Less Than (Unsigned): jltu $addr \rightarrow jnc addr$

Skip N instructions: [JMP] skip(N) \rightarrow [JMP] pc + N + 1

Call subroutine:

call Addr16 X1111000XXXX0001 push(PC+1); PC = Addr16

Operations on each clock cycle:

Fetch instruction Fetch and update SP Fetch new address Store PC in stack into PC Load new address	Feto	tch instruction	·	Store PC in stack	Load new address into PC
---	------	-----------------	---	-------------------	--------------------------

Description:

The call instruction pushes the address of the <u>next</u> instruction to the stack before jumping unconditionally to an address.

Since the PC is pushed to the stack in data memory, arbitrary depths of subroutine calls are allowed (as well as recursion).

Macros:

System Call*: syscall Addr16 \rightarrow call Addr16

Return from subroutine:

ret	X1111001XXXX0001 XXXXXXXXXXXXXXXX	PC = pop()
-----	--------------------------------------	------------

Operations on each clock cycle:

Fetch instruction	Fetch and update Stack Pointer	Pop new address from stack and load it into PC
-------------------	--------------------------------	--

Description:

The ret instruction pops the top of the stack and jumps unconditionally to that address.

<u>Warning</u>: Make sure the subroutine has freed all the memory it had allocated in the stack before using ret (otherwise sp won't be pointing to the correct return address).
